OWASP

Broken access controls are a type of security vulnerability that arises when an application or system fails to properly restrict access to sensitive data or functionality. This vulnerability allows attackers to gain unauthorized access to resources that should be restricted, such as user accounts, files, databases, or administrative functions. Broken access controls can occur due to a variety of factors, including poor design, configuration errors, or coding mistakes.

Objectives that the student will learn:

1. Understand what Broken Access Control is and its impact.
2. Identify Broken Access Control vulnerabilities in web applications.
3. Exploit these vulnerabilities in a controlled environment.
4. Understand and apply measures to mitigate and prevent these vulnerabilities.

Pre-requisites:

1. Basic understanding of JSON, web applications, and HTTP protocols.
2. Familiarity with scripting languages such as PHP and JavaScript.
3. Knowledge of web application security standards and frameworks such as OWASP Top 10.
4. Basic understanding and usage of a proxy tool like Burp Suite.

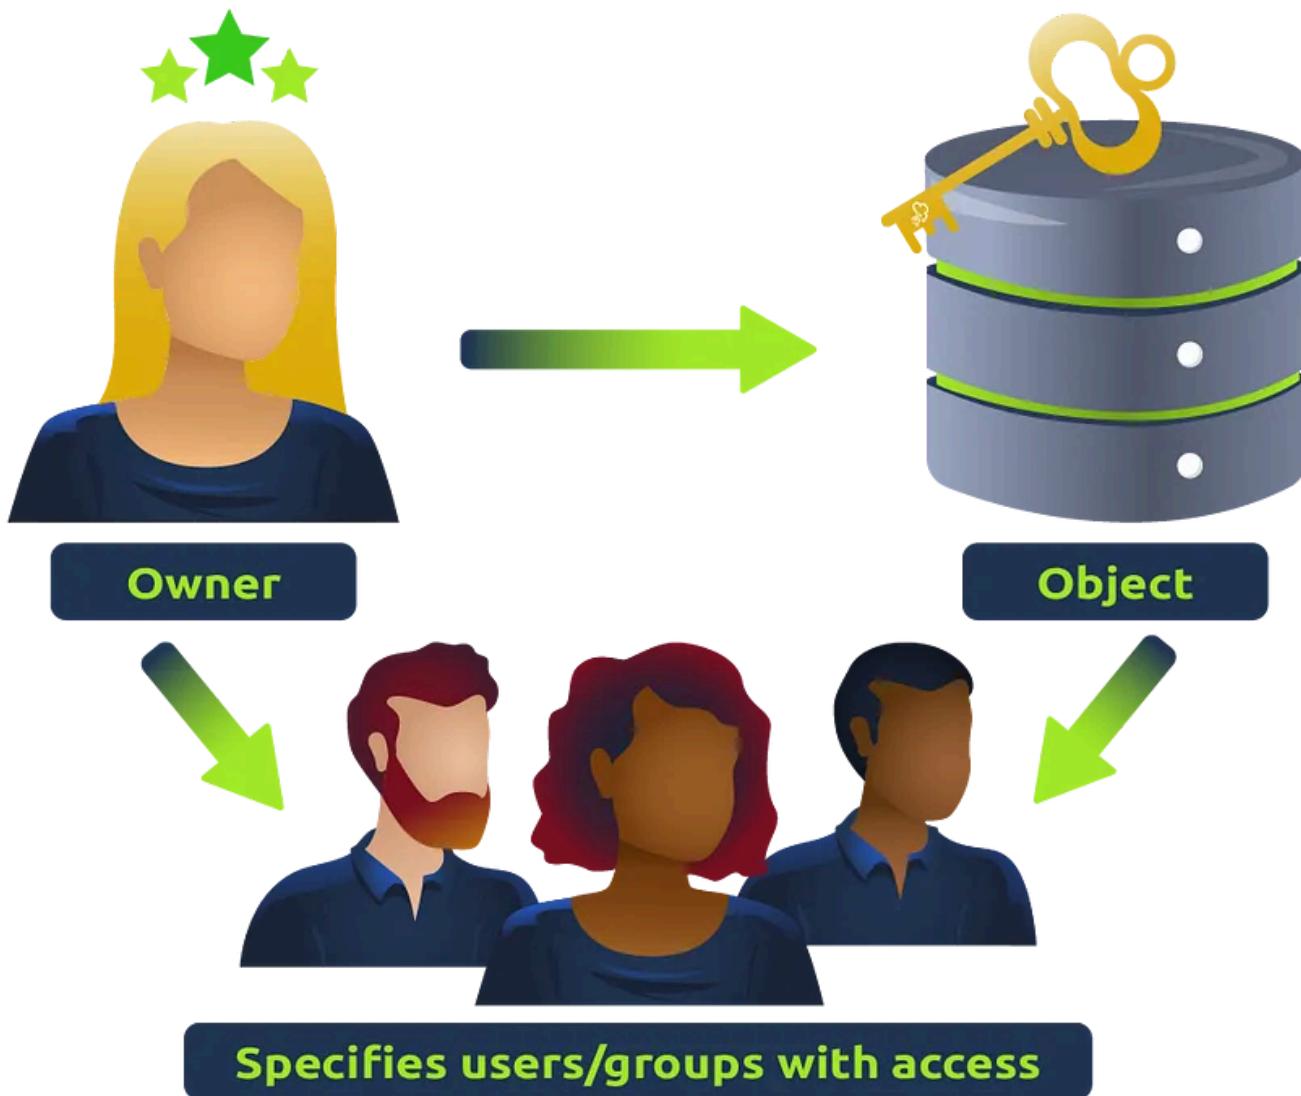

What is Access Control?

Access control is a security mechanism used to control which users or systems are allowed to access a particular resource or system. Access control is implemented in computer systems to ensure that only authorized users have access to resources, such as files, directories, databases, and web pages. The primary goal of access control is to protect sensitive data and ensure that it is only accessible to those who are authorized to access it.

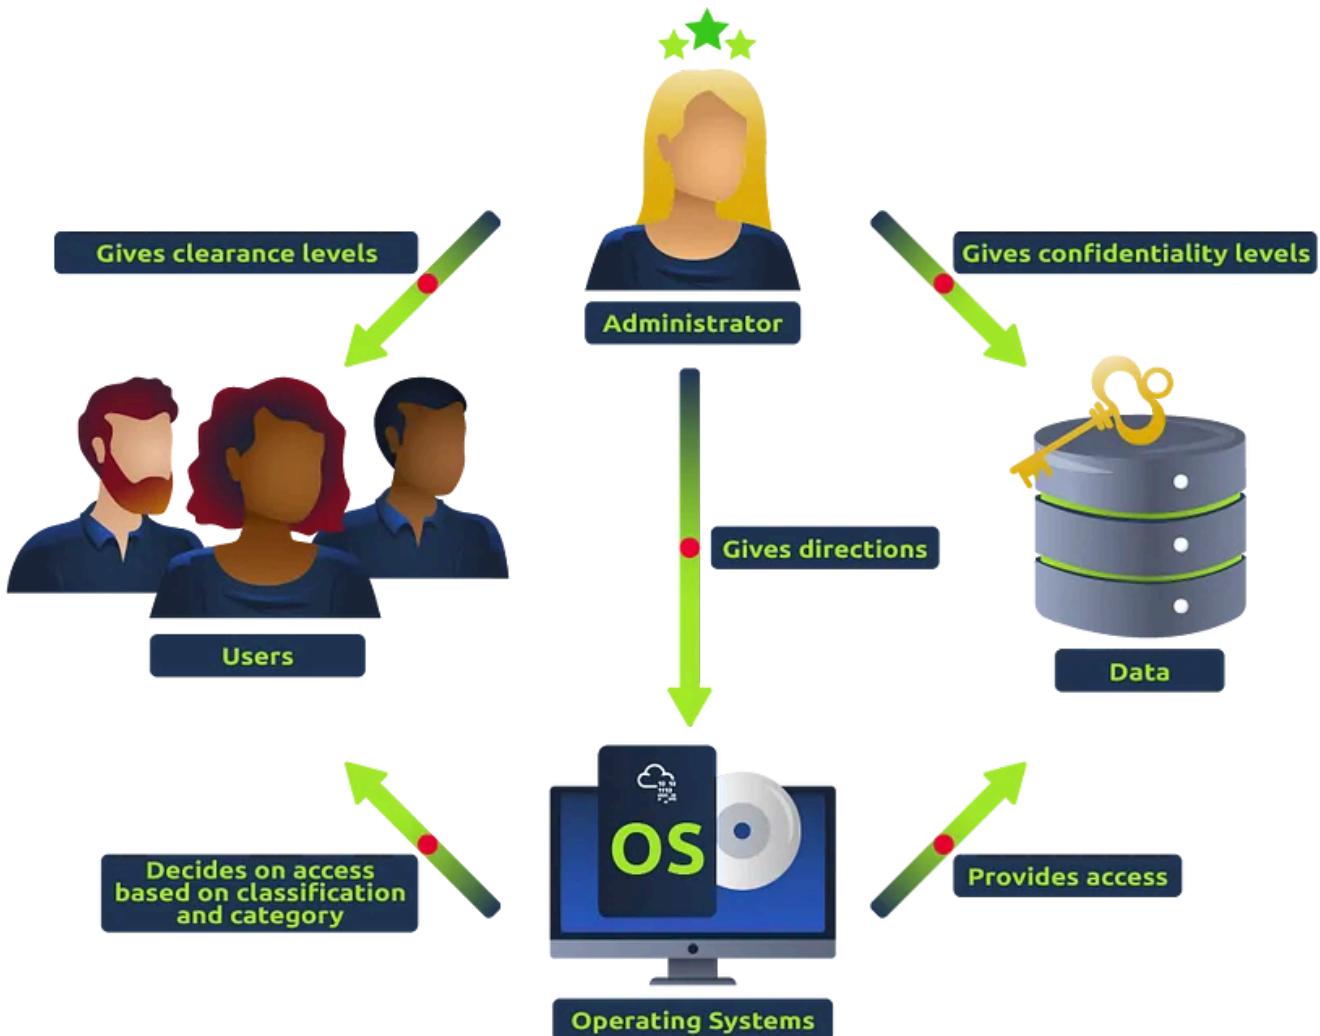

Access control can be implemented in different ways, depending on the type of resource being protected and the security requirements of the system. Some common access control mechanisms include:

Discretionary Access Control (DAC):

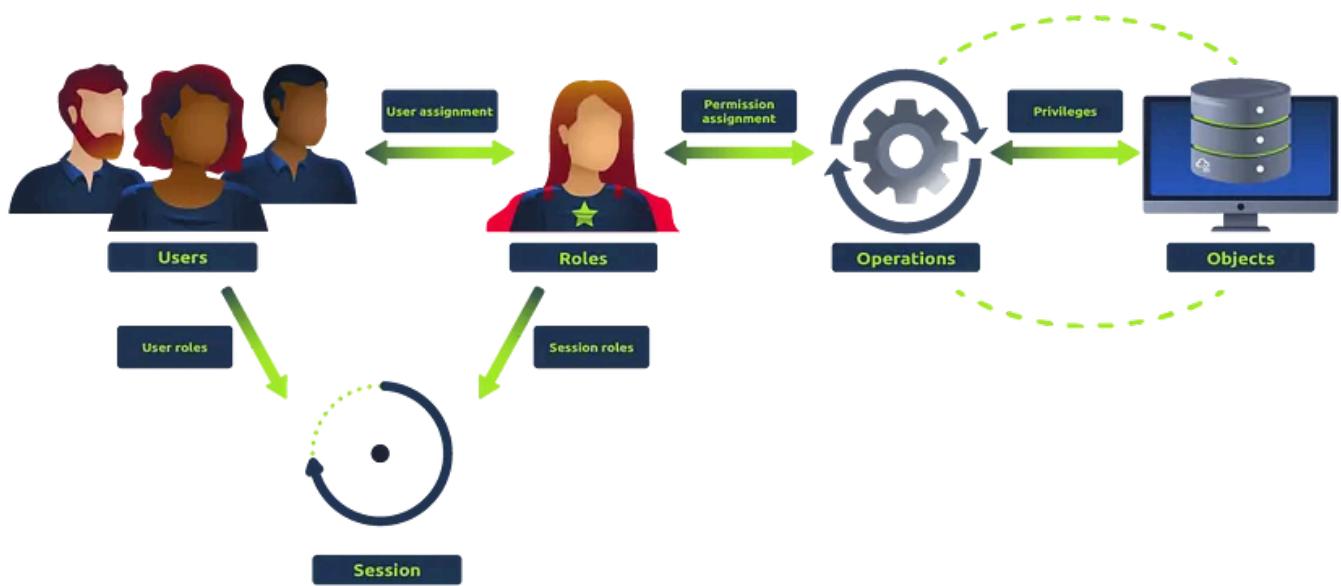

In this type of access control, the resource owner or administrator determines who is allowed to access a resource and what actions they are allowed to perform. DAC is commonly used in operating systems and file systems. In layman's terms, imagine a castle where the king can give keys to his advisors, allowing them to open any doors they like, whenever they want. That's DAC for you. It's the liberty to control access to your own resources. The one in charge, like the king of the castle, can hand out permissions to whomever they please, dictating who can come in and out.

Mandatory Access Control (MAC):

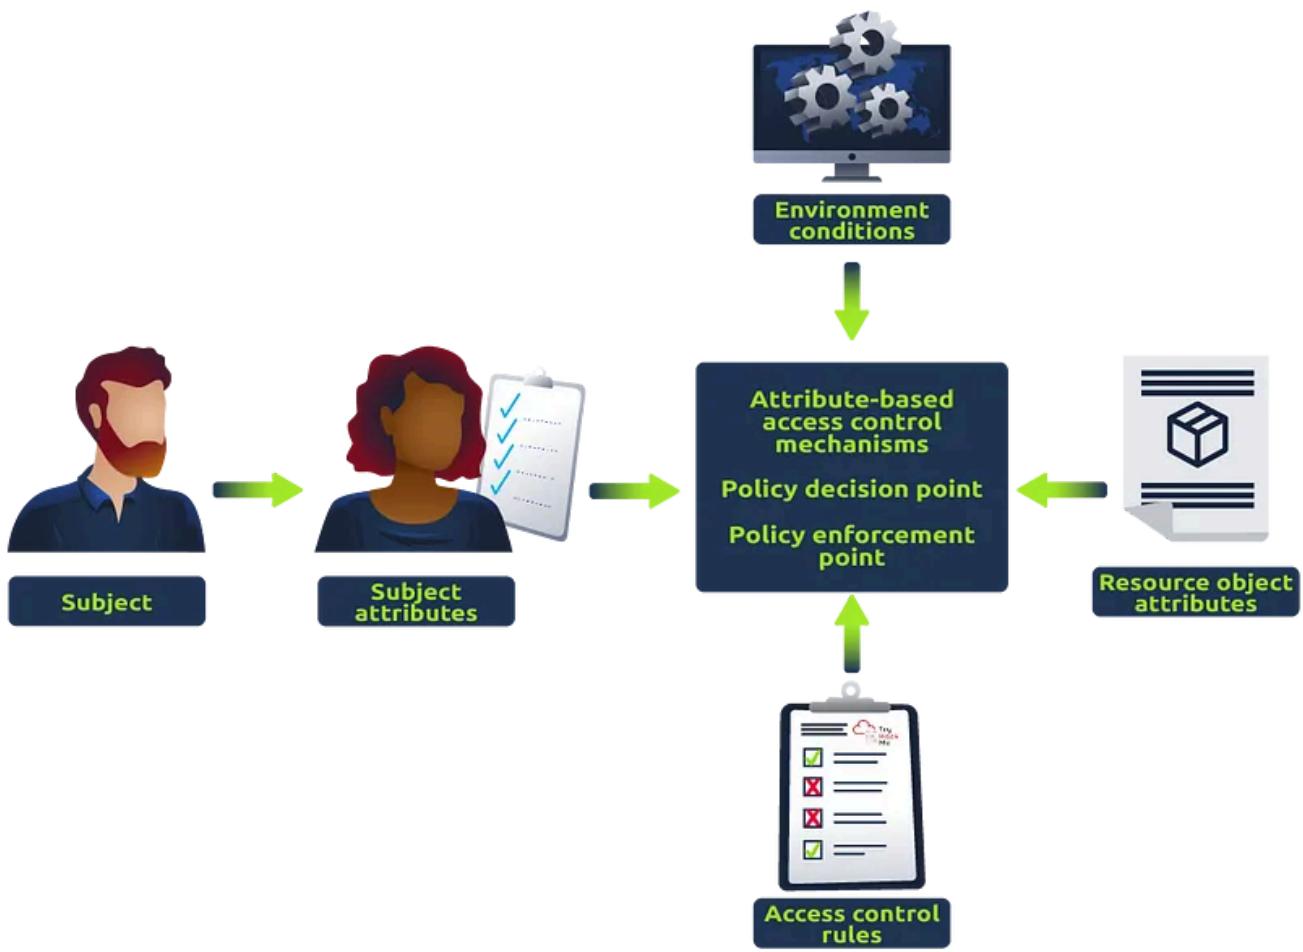

this type of access control, access to resources is determined by a set of predefined rules or policies that are enforced by the system. MAC is commonly used in highly secure environments, such as government and military systems. In layman's terms, picture a fort with an iron-clad security protocol. Only specific individuals with particular security clearances can access certain areas, and this is non-negotiable. The high commander sets the rules, and they are rigorously followed. That's how MAC works. It's like the stern security officer who allows no exceptions to the rule.

Role-Based Access Control (RBAC):

In this type of access control, users are assigned roles that define their level of access to resources. RBAC is commonly used in enterprise systems, where users have different levels of authority based on their job responsibilities. In layman's terms, imagine a modern corporation. You have your managers, your executives, your sales staff, etc. They each have different access to the building. Some can enter the boardroom, others can access the sales floor, and so on. That's the essence of RBAC — assigning access based on a person's role within an organization.

Attribute-Based Access Control (ABAC):

In this type of access control, access to resources is determined by a set of attributes, such as user role, time of day, location, and device. ABAC is commonly used in cloud environments and web applications. In layman's terms, think of a highly advanced sci-fi security system that scans individuals for certain attributes. Maybe it checks whether they're from a particular planet, whether they're carrying a specific device, or if they're trying to access a resource at a specific time. That's ABAC. It's like the smart, flexible security of the future.

Implementing access control can help prevent security breaches and unauthorized access to sensitive data. However, access control is not foolproof and can be vulnerable to various types of attacks, such as privilege escalation and broken access control vulnerabilities. Therefore, it is important to regularly review and test access control mechanisms to ensure that they are working as intended.

Broken Access Control:

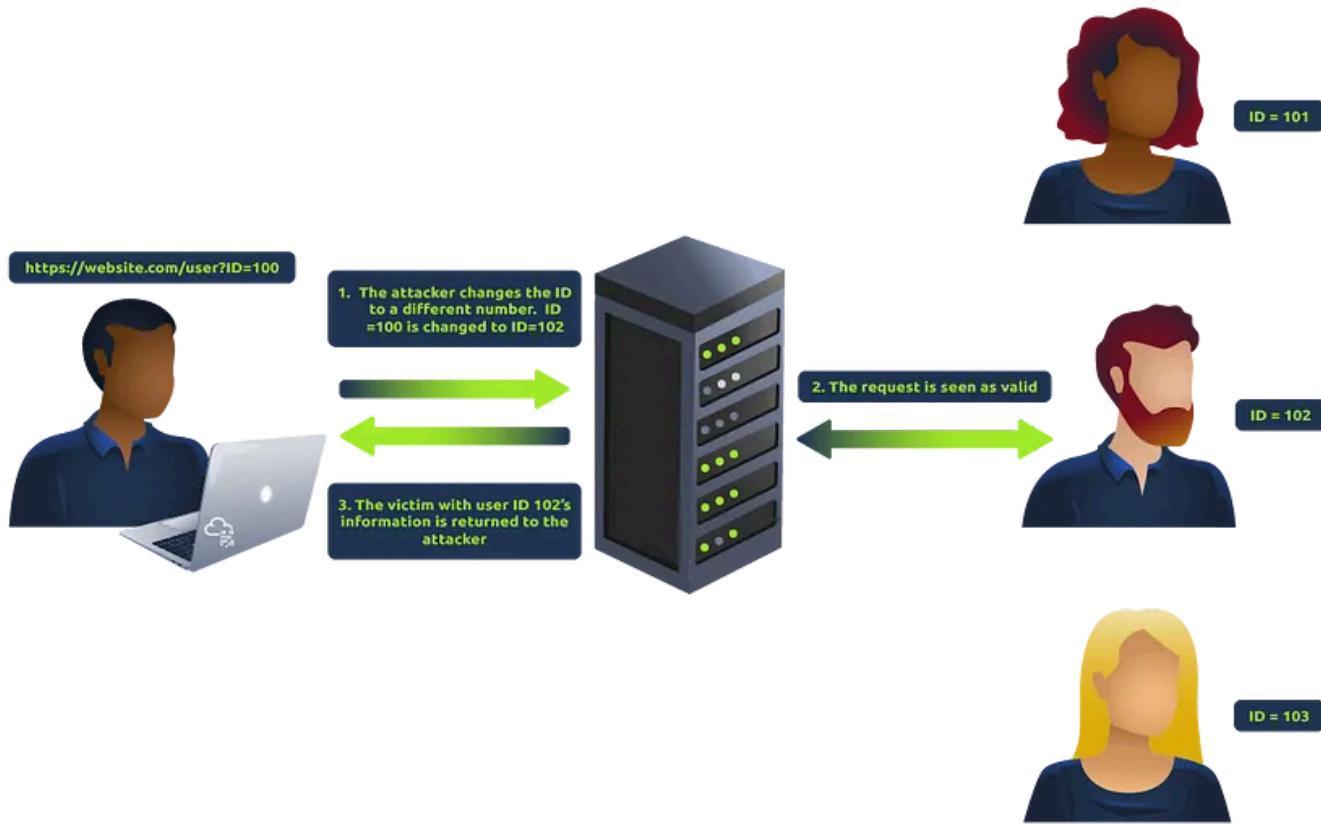

Broken access control vulnerabilities refer to situations where access control mechanisms fail to enforce proper restrictions on user access to resources or data. Here are some common exploits for broken access control and examples:

Horizontal privilege escalation occurs when an attacker can access resources or data belonging to other users with the same level of access. For example, a user might be able to access another user's account by changing the user ID in the URL.

Vertical privilege escalation occurs when an attacker can access resources or data belonging to users with higher access levels. For example, a regular user can access administrative functions by manipulating a hidden form field or URL parameter.

Insufficient access control checks occur when access control checks are not performed correctly or consistently, allowing an attacker to bypass them. For example, an application might allow users to view sensitive data without verifying their proper permissions.

Insecure direct object references occur when an attacker can access a resource or data by exploiting a weakness in the application's access control mechanisms. For example, an application might use predictable or easily guessable identifiers for sensitive data, making it easier for an attacker to access. You may refer to this [room](#) in **Task #4** to learn more about this.

These exploits can be prevented by implementing strong access control mechanisms and regularly reviewing and testing them to ensure they are functioning as intended.

Let's get started with the task:

Question:

What is IDOR?

Answer: Insecure Direct Object Reference

An IDOR Vulnerability is a type of broken access control vulnerability.

Question:

What occurs when an attacker can access resources or data belonging to other users with the same level of access?

Answer: horizontal privilege escalation

Please refer to the horizontal privilege escalation section to get the answer to this question.

Question:

What occurs when an attacker can access resources or data from users with higher access levels?

Answer: vertical privilege escalation

Please refer to the vertical privilege escalation section to get the answer to this question.

Question:

What is ABAC?

Answer: attribute-based access control

Please refer to the attribute-based access control section to get the answer to this question.

Question:

What is RBAC?

Answer: Role-based access control

Please refer to the role-based access control section to get the answer to this question.

Please register an account by visiting the tryhackme machine-ip and intercept the login request. Send the request to repeater. Please refer to the below screenshot.

The screenshot shows the Burp Suite interface with the following details:

Request:

```
1 [GET /dashboard.php HTTP/1.1
2 Host: 10.10.26.229
3 User-Agent: Mozilla/5.0 (X11; Ubuntu; Linux x86_64; rv:109.0) Gecko/20100101 Firefox/109.0
4 Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/avif,image/webp,*/*;q=0.8
5 Accept-Language: en-US,en;q=0.5
6 Accept-Encoding: gzip, deflate
7 Referer: http://10.10.26.229/login.php?result=Registration%20successful
8 Connection: close
9 Cookie: PHPSESSID=c23dffff714bd1527c8fd0f74b40a5a2d
10 Upgrade-Insecure-Requests: 1
11
12
```

Response:

```
1 HTTP/1.1 200 OK
2 Date: Mon, 08 Jan 2024 11:18:18 GMT
3 Server: Apache/2.4.38 (Debian)
4 X-Powered-By: PHP/8.0.19
5 Expires: Thu, 19 Nov 1981 08:52:00 GMT
6 Cache-Control: no-store, no-cache, must-revalidate
7 Pragma: no-cache
8 Vary: Accept-Encoding
9 Content-Length: 1404
10 Connection: close
11 Content-Type: text/html; charset=UTF-8
12
13 <!DOCTYPE html>
14 <html lang="en">
15   <head>
16     <meta charset="UTF-8">
17     <meta http-equiv="X-UA-Compatible" content="IE=edge">
18     <meta name="viewport" content="width=device-width, initial-scale=1.0">

Question:

What is the type of server that is hosting the web application? This can be found in the response of the request in Burp Suite.

Answer: apache

In the captured request, look at the response. We will get the type of server and its version number which is the answer to this question. Please refer to the below screenshot. The answer is highlighted in the screenshot.

The screenshot shows the Burp Suite interface with the following details:

- Request:**

```
1 GET /dashboard.php HTTP/1.1
2 Host: 10.10.26.229
3 User-Agent: Mozilla/5.0 (X11; Ubuntu; Linux x86_64; rv:109.0) Gecko/20100101 Firefox/109.0
4 Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/avif,image/webp,*/*;q=0.8
5 Accept-Language: en-US,en;q=0.5
6 Accept-Encoding: gzip, deflate
7 Referer: http://10.10.26.229/login.php?result=Registration%20successful
8 Connection: close
9 Cookie: PHPSESSID=c23dffff714bd1527c8fd0f74b40a5a2d
10 Upgrade-Insecure-Requests: 1
11
12
```
- Response:**

```
1 HTTP/1.1 200 OK
2 Date: Mon, 08 Jan 2024 11:18:18 GMT
3 Server: Apache/2.4.38 (Debian)
4 X-Powered-By: PHP/8.0.19
5 Expires: Thu, 19 Nov 1981 08:52:00 GMT
6 Cache-Control: no-store, no-cache, must-revalidate
7 Pragma: no-cache
8 Vary: Accept-Encoding
9 Content-Length: 1404
10 Connection: close
11 Content-Type: text/html; charset=UTF-8
12
13 <!DOCTYPE html>
14 <html lang="en">
15   <head>
16     <meta charset="UTF-8">
17     <meta http-equiv="X-UA-Compatible" content="IE=edge">
18     <meta name="viewport" content="width=device-width, initial-scale=1.0">
19   <title>
20     Dashboard
21   </title>
22   <link rel="stylesheet" href="styles.css">
23 </head>
24 <body>
25   <div class="container">
26     <div class="content">
27       <a id="link" class="logout" href="logout.php">
          Logout
        </a>
      <h1>
        Welcome, test
      </h1>
      <h2>
```
- Inspector:**
 - Selected text: Server: Apache/2.4.38 (Debian)
 - Request attributes: 2
 - Request query parameters: 0
 - Request body parameters: 0
 - Request cookies: 1
 - Request headers: 9
 - Response headers: 10

Question:

What is the name of the parameter in the JSON response from the login request that contains a redirect link?

Answer: redirect_link

Capture the login request and send it to the repeater.

Observe the response, where you will get the parameter name that contains a redirect link which is the answer to this question.

Please refer to the below screenshot.

The screenshot shows the Burp Suite interface with the following details:

Request:

```

1 POST /functions.php HTTP/1.1
2 Host: 10.10.26.229
3 User-Agent: Mozilla/5.0 (X11; Ubuntu; Linux x86_64; rv:109.0)
4 Accept: application/json, text/javascript, */*; q=0.01
5 Accept-Language: en-US,en;q=0.5
6 Accept-Encoding: gzip, deflate
7 Content-Type: application/x-www-form-urlencoded; charset=UTF-8
8 X-Requested-With: XMLHttpRequest
9 Content-Length: 55
10 Origin: http://10.10.26.229
11 Connection: close
12 Referer: http://10.10.26.229/login.php
13 Cookie: PHPSESSID=c23dff714bd1527c0fd0f74b40a5a2d
14
15 username=test1%40test.com&password=test1&function=login

```

Response:

```

1 HTTP/1.1 200 OK
2 Date: Mon, 08 Jan 2024 11:29:48 GMT
3 Server: Apache/2.4.38 (Debian)
4 X-Powered-By: PHP/8.0.19
5 Expires: Thu, 19 Nov 1981 08:52:00 GMT
6 Cache-Control: no-store, no-cache, must-revalidate
7 Pragma: no-cache
8 Vary: Accept-Encoding
9 Content-Length: 153
10 Connection: close
11 Content-Type: text/html; charset=UTF-8
12
13 {"status": "success", "message": "Login successful", "is_admin": "false", "first_name": "test", "last_name": "test", "Redirect_link": "dashboard.php?isadmin=false"}

```

Inspector Panel:

- Selected text: redirect_link
- Request attributes: 2
- Request query parameters: 0
- Request body parameters: 3
- Request cookies: 1
- Request headers: 12
- Response headers: 10

Question:

What Burp Suite module allows us to capture requests and responses between ourselves and our target?

Answer: proxy

Question:

What is the admin's email that can be found in the online users' table?

Answer: admin@admin.com

Please login to the dashboard. There will be the section below where you can get the answer to this question. Please refer to the screenshot below.

The screenshot shows a Firefox browser window with the title "Dashboard — Mozilla Firefox". The address bar displays the URL 10.10.26.229/dashboard.php. The main content area of the dashboard includes:

- A welcome message: **Welcome, test**
- A section titled **Announcements** containing a status update from "admin" stating "Application building in progress".
- A section titled **Report the bugs** with instructions to email "admin@admin.com" for bugs.
- An "Online users" section showing one user: admin@admin.com.

Now looking at the url of the redirect_link, paste the url directly in a new tab and look at the parameter passed in the url.

Next questions are based on the url parameter.

Question:

What kind of privilege escalation happened after accessing admin.php?

Answer: Vertical

Here, the attack type is vertical privilege escalation because we are escalating our privileges from user level to admin level.

Question:

What parameter allows the attacker to access the admin page?

Answer: isadmin

The answer to this question lies in the url itself.

Question:

What is the flag in the admin page?

Answer: THM{I_C4n_3xpl01t_B4c}

Copy the url and modify the parameter value from “isadmin=false” to “isadmin=true” and forward the request. Please look at the below screenshot.

Email	First Name	Last Name	Auth level	Delete	Admin access
admin@admin.com	admin		Admin	<input type="checkbox"/>	<input checked="" type="checkbox"/>
test1@test.com	test	test	Normal	<input type="checkbox"/>	<input type="checkbox"/>

Mitigation

There are several steps that can be taken to mitigate the risk of broken access control vulnerabilities in PHP applications:

Implement Role-Based Access Control (RBAC): Role-based access control (RBAC) is a method of regulating access to computer or network resources based on the roles of individual users within an enterprise. By defining roles in an organization and assigning access rights to these roles, you can control what actions a user can

perform on a system. The provided code snippet illustrates how you can define roles (such as ‘admin’, ‘editor’, or ‘user’) and the permissions associated with them. The `hasPermission` function checks if a user of a certain role has a specified permission.

```
// Define roles and permissions
$roles = [
    'admin' => ['create', 'read', 'update', 'delete'],
    'editor' => ['create', 'read', 'update'],
    'user' => ['read'],
];

// Check user permissions
function hasPermission($userRole, $requiredPermission) {
    global $roles;
    return in_array($requiredPermission, $roles[$userRole]);
}

// Example usage
if (hasPermission('admin', 'delete')) {
    // Allow delete operation
} else {
    // Deny delete operation
}
```

Use Parameterized Queries: Parameterized queries are a way to protect PHP applications from SQL Injection attacks, where malicious users could potentially gain unauthorized access to your database. By using placeholders instead of directly including user input into the SQL query, you can significantly reduce the risk of SQL Injection attacks. The provided example demonstrates how a query can be made secure using prepared statements, which separates SQL syntax from data and handles user input safely.

Sample Code

```
// Example of vulnerable query
$username = $_POST['username'];
$password = $_POST['password'];
$query = "SELECT * FROM users WHERE username='$username' AND
password='$password'";

// Example of secure query using prepared statements
$username = $_POST['username'];
$password = $_POST['password'];
$stmt = $pdo->prepare("SELECT * FROM users WHERE username=? AND
password=?");
$stmt->execute([$username, $password]);
$user = $stmt->fetch();
```

Proper Session Management: Proper session management ensures that authenticated users have timely and appropriate access to resources, thereby reducing the risk of unauthorized access to sensitive information. Session management includes using secure cookies, setting session timeouts, and limiting the number of active sessions a user can have. The code snippet shows how to initialize a session, set session variables and check for session validity by looking at the last activity time.

Sample Code

```
// Start session
session_start();

// Set session variables
$_SESSION['user_id'] = $user_id;
$_SESSION['last_activity'] = time();

// Check if session is still valid
if (isset($_SESSION['last_activity']) && (time() -
$_SESSION['last_activity'] > 1800)) {
    // Session has expired
    session_unset();
    session_destroy();
}
```

Use Secure Coding Practices: Secure coding practices involve methods to prevent the introduction of security vulnerabilities. Developers should sanitize and validate user input to prevent malicious data from causing harm and avoid using insecure functions or libraries. The given example shows how to sanitize user input using PHP's `filter_input` function and demonstrates how to securely hash a password using `password_hash` instead of an insecure function like `md5`.

The screenshot shows a terminal window titled "Sample Code". The code displayed is:

```
// Validate user input
$username = filter_input(INPUT_POST, 'username',
FILTER_SANITIZE_STRING);
$password = filter_input(INPUT_POST, 'password',
FILTER_SANITIZE_STRING);
```

[Open in app ↗](#)

Medium

Search

```
$password = hash($password),
// Example of secure code using password_hash
$password = password_hash($password, PASSWORD_DEFAULT);
```

Conclusion

Broken access control is a security vulnerability that occurs when a system fails to properly enforce access controls, which can result in unauthorized users gaining access to sensitive information or performing actions they are not authorized to do.

Horizontal privilege escalation occurs when a user is able to access data or perform actions that they are not authorized to do within their own privilege level. This can be dangerous because it can allow an attacker who has already gained access to the system to move laterally through the network and access additional resources or sensitive data.

Vertical privilege escalation occurs when a user is able to gain access to data or perform actions that are reserved for users with higher privilege levels, such as system administrators. This can be even more dangerous because it can allow an attacker to gain full control of the system and potentially take over the entire network.

The impact of these types of privilege escalation can vary depending on the specific system and the level of access that is gained. However, in general, the consequences can include unauthorized access to sensitive information, data loss or theft, disruption of critical systems or services, and even complete network compromise. Therefore, it is important to implement strong access controls and regularly monitor for any signs of unauthorized access or activity.

Thank Your for reading !

Happy Hacking !
